

THE CURRENCY OF YOU

SunRey Coin & the Human Information Network

A RIGHTS-GOVERNED ECONOMIC ARCHITECTURE FOR HUMAN INFORMATION AND CONTRIBUTION

A technical and economic white paper on permission authority, verified contribution, compute-to-data, contribution valuation, compensation, privacy, and the boundary between human economic value and monetary authority.

Person → Permission → Verified Contribution → Authorized Economic Use → Compensation / Participation

SUNREY TECHNICAL WHITE PAPER | SEPTEMBER 2026

Public architecture paper. Conceptual design; regulated capabilities and production monetary parameters remain subject to legal, security, governance, and jurisdiction-specific approval.

FOUNDATIONAL THESIS

Abstract

The digital economy has learned to extract enormous value from human information. SunRey proposes a different architecture: make the individual the permission authority, make authorized contribution - not the person - the economic object, and make rights, purpose, provenance, verification and compensation machine-manageable without permanently publishing sensitive raw data.

SunRey Coin is the native economic coordination asset for this human economic layer. Its underlying network, the Human Information Network (HIN), is not designed as a marketplace in people or a claim that personal data is collateral. It is designed as a rights-governed network in which verified human contribution can participate economically when a specific use is authorized.

PERSON	PERMISSION	VERIFIED CONTRIBUTION	AUTHORIZED USE	COMPENSATION
--------	------------	--------------------------	----------------	--------------

The canonical HIN sequence: economic participation begins with permission and verifiable contribution, not data possession.

The architecture separates five things that conventional data markets often collapse: identity, information, rights, contribution value, and money. Sensitive source data can remain encrypted in a Personal Data Vault. A Purpose Firewall evaluates why an operation is requested. A Consent Ledger records granular authorization. Privacy Clean Rooms support computation-in-place. Proof of Contribution and provenance establish what occurred. The Personal Economic Value Engine (PEVE) estimates the market value of a specific authorized contribution. A separate monetary governance path determines whether and how native-asset settlement may occur.

Core invariant

Human worth is not contribution value. Contribution value is not SunRey Coin market price. Valuation is not monetary authority. Information may support an economic claim, but information alone cannot create money.

CORE PRINCIPLES

The Architecture in One Page

SunRey treats human information as governed economic context rather than a resource that becomes monetizable merely because a platform possesses it.

#	Principle	Architectural consequence
1	The person is the permission authority	Possession or technical access never implies permission to use information.
2	Value the contribution, not the person	The system evaluates a defined authorized contribution in a defined context.
3	Raw data stays protected by default	Sensitive source material remains in protected storage or controlled compute environments.
4	Purpose is executable	Every sensitive use declares requester, purpose, jurisdiction, duration, and permitted outputs.
5	Verification precedes valuation	A contribution must be attributable, evidence-backed, and unique before it can be economically valued.
6	PEVE is not monetary authority	A contribution valuation may inform compensation or a monetary proposal but cannot itself issue SunRey.
7	One SunRey Coin remains one SunRey Coin	The token remains fungible; contribution differences change compensation amounts, not per-owner token exchange value.
8	Audit without publishing the dossier	Evidence, rights, policy and settlement commitments can be anchored while sensitive source data remains off-chain.

North-star design

Put your money and your information to work for you - while preserving the individual as the center of the rights model.

ECONOMIC CONTEXT

1. Why a Human Information Economy Needs a New Rights Model

AI systems become more useful as they understand context. The strategic question is who controls that context, how it may be used, and who participates economically when it creates value.

Traditional digital platforms frequently treat information collection, service access, analytics, advertising, model training and monetization as tightly coupled. The user may receive a service, but the economic rights surrounding downstream information use can be opaque. SunRey starts from the opposite direction: the existence of data does not create a blanket economic right to use it.

The HIN is designed for a post-AI economy in which human intent, verified credentials, goals, preferences, authorized behavioral context, research participation and other contributions may be economically useful to enterprises and AI systems. But usefulness is not sufficient. The architecture requires a rights path: what is being requested, from whom, for which purpose, for how long, in which jurisdiction, under what privacy constraints, and with what compensation or participation terms?

Design problem

How can an economic network make human information useful to computation and markets without turning the individual into an irreversible data asset?

The SunRey answer is to shift the scarce economic object away from the raw dossier and toward verified, purpose-bound rights and outputs. This makes permission, provenance, computation and compensation part of the economic transaction itself.

HUMAN ECONOMIC LAYER

2. The Currency of You Thesis

"The Currency of You" does not mean pricing a human being. It means creating an economic layer in which people can authorize, verify and participate in the value created by specific contributions.

IDENTITY	RIGHTS	CONTRIBUTION	VERIFICATION	VALUE	SETTLEMENT
----------	--------	--------------	--------------	-------	------------

A human-information economy requires a chain of authority, not a shortcut from data to token.

SunRey Coin coordinates the human-information and participation economy. Representative sources of authorized economic activity can include verified credentials, research participation, professional and educational contribution, preferences and consumer intent, authorized financial context, user-declared goals, community participation, AI interactions, and permissioned outputs derived through controlled computation.

The token is therefore positioned as a network coordination and settlement asset, not a claim of ownership over a person or their raw personal data. The intended value driver is useful network activity: rights transactions, rewards, compute requests, verified contribution, research participation, attestations, settlement and other authorized human economic activity.

HIN principle

Person -> Permission -> Verified Contribution -> Authorized Economic Use -> Compensation / Participation

This sequence is the essential intellectual positioning. It places permission before economic use and contribution before compensation. It also creates explicit places for verification, privacy controls, policy and audit to operate.

NON-NEGOTIABLE BOUNDARY

3. Human Worth vs. Contribution Value

The Human Information Network is designed to reject the idea that the economic system should calculate an intrinsic score for a person.

Age, health, DNA, psychology, location, social relationships and other sensitive characteristics do not become economic contributions merely because information about them exists. Where sensitive information participates in an authorized research or computation event, the monetizable object is the authorized contribution or computation event - not the underlying human characteristic.

Concept	Meaning	Rule
Human worth	Intrinsic moral or social value of a person	Outside the system; never computed.
Personal attribute	A fact or characteristic about a person	Protected context; not automatically economic.
Authorized contribution	A specific act, dataset slice, credential, response, computation participation or verified output used for an allowed purpose	Eligible for verification and valuation.
Contribution value	Context-specific economic estimate for the authorized contribution	Calculated under a versioned methodology.
SunRey Coin quantity	A governed settlement or reward amount where permitted	Downstream of valuation and monetary policy.
SunRey market price	Exchange value formed in permitted markets	Separate from contribution valuation.

Safety rule

No protected trait, person-level desirability construct, social-credit concept or generalized human-worth score should become a shortcut into contribution valuation or token issuance.

SYSTEM OVERVIEW

4. Human Information Network Architecture

HIN is a permission-aware network that connects identity, rights, verified contributions, protected data, computation, provenance, valuation and compensation while preserving distinct authorities.

Layer	Function
Identity & Participant Layer	Login, wallet, pseudonymous human economic identity, enterprise identity, agent identity and governance identity.
Vault & Protected Data	Segmented encrypted source data and user-linked protected storage.
Rights & Consent	Granular rights grants, consent objects, purpose, duration, revocation, compensation and derivative-use terms.
Personal Economic Graph	Permission-aware relationships among authorized facts, goals, credentials, financial context and opportunities.
Clean Room / Compute-to-Data	Approved queries or models execute near protected data and return only allowed outputs.
Contribution Registry	Canonical contribution identity, provenance, uniqueness, challenge state and monetization state.
Attestation & Evidence	Source-specific verification, signed receipts, credential references, lineage and proof commitments.
PEVE	Versioned valuation of a specific authorized contribution.
SunRey Protocol	Rights, policy, evidence and monetary governance determine permitted settlement and final state.

Authority separation

The HIN can observe, connect, verify and value. It is not a license for any database, AI model, oracle, frontend or analytics service to become monetary authority.

WHO IS ACTING?

5. Identity, Pseudonymity & Participant Separation

SunRey separates identities by function so public economic participation does not require unnecessary exposure of legal identity.

Identity plane	Purpose	Boundary
Login identity	Access to SunRey applications and services.	Authentication and session security.
Wallet identity	Addresses or custody references used for native-asset activity.	May be multiple per human.
Human economic identity	Canonical participant identity used to attribute contributions and prevent duplication.	Can be pseudonymous while linked to assurance evidence.
Governance identity	Identity permitted to participate in high-consequence protocol or policy decisions.	Separate authorization and key controls.
Enterprise identity	Researcher, buyer, institution or service participant.	Licensing, purpose and contractual state.
AI-agent identity	Registered software actor acting under a controller and capability limits.	Cannot silently become the human or governance authority.

A single human may control multiple wallets without multiplying a contribution. Contribution uniqueness attaches to the canonical participant/contribution event rather than to the number of accounts or addresses. This enables wallet flexibility while defending the economic layer against identity multiplication.

Privacy objective

Prove enough identity to establish attribution, rights and uniqueness - expose no more identity than the transaction requires.

PROTECTED SOURCE LAYER

6. Personal Data Vault & Raw-Data Isolation

Sensitive information should remain protected by default. SunRey is designed to move permissions and computation toward the data rather than routinely moving raw data toward every buyer or model.

The Personal Data Vault is the protected source layer for categories such as identity, financial context, work and skills, consumption, user-declared goals, mobility, lifestyle and - only where lawful and explicitly authorized - health, wellness, biological or other sensitive data. The architecture is segmented so the existence of one category does not imply access to another.

Control	Objective
Encryption & segmentation	Separate sensitive categories and reduce the impact of compromise or overbroad access.
Minimal disclosure	Return only the attributes or outputs required for the authorized purpose.
No public raw-data publication	The blockchain can anchor hashes, rights, receipts, provenance and settlement evidence while source records remain protected.
Controlled export	User export or portability does not imply unrestricted marketplace resale.
Retention & deletion controls	Operational handling follows applicable rights and policy while finalized historical proof records remain append-only where required.
Compute-near-data	Clean-room execution can keep source material inside a controlled environment.

Raw-data rule

Sensitive personal source data is not the native on-chain asset. Rights, permissions, attestations, proof references and permitted outputs are the economic primitives.

RIGHTS BEFORE USE

7. Permission Authority & Consent Ledger

The HIN treats the individual as the permission authority. Authorization is a durable economic object, not a one-time interface checkbox.

A granular consent object can specify the data categories, permitted purpose, requester, authorized compute, jurisdiction, duration, compensation terms, AI-training status, resale or derivative use, revocation rules and other constraints. This lets two requests for the same underlying information produce different outcomes because their purpose, scope or legal context differs.

Consent field	Economic meaning
Data categories	Exactly which sources or derived attributes are in scope.
Purpose	Research, product testing, analytics, personalization, advertising, AI training or another declared use - separately controlled.
Requester	Enterprise, researcher, agent, service or other identified actor.
Duration	Time-limited permission rather than indefinite possession.
Jurisdiction	Where the participant, requester and compute environment may operate.
Compensation	Minimum, clearing or agreed economic participation terms.
Derivative / resale	Explicitly allowed, constrained or prohibited.
Revocation	Stops future use where required; does not silently rewrite valid historical events.

Rights principle

A factual statement can be true while its use remains unauthorized. Truth and permission are separate states.

WHY IS THIS USE ALLOWED?

8. Purpose Firewall & Relationship Authorization

Possession of information never implies permission to use it. The Purpose Firewall makes that distinction executable.

Every sensitive request should declare who is requesting, what information or relationship is requested, why it is requested, for how long, under which jurisdiction and policy, which model or agent will operate, and what output is allowed. The firewall then evaluates those dimensions against consent, product policy, legal capability and data sensitivity.

Request class	Example purpose boundary
Research use	May permit cohort eligibility or compute-to-data while blocking advertising and resale.
Advertising use	Can remain disabled even if the same information is permitted for another purpose.
AI training	Separately controlled; permission for inference or analysis does not automatically imply training rights.
Financial personalization	Can use authorized economic context under the user mandate without granting enterprise data-market rights.
Monetary proposal	Requires a distinct authorization path; permission for research does not automatically authorize a supply-changing use.

Purpose firewall test

What may be known? What may be used? By whom? For what purpose? For how long? In which jurisdiction? With which output and compensation terms?

PERMISSION-AWARE CONTEXT

9. Personal Economic Graph

The Personal Economic Graph connects authorized facts and relationships so agents and economic services can reason over context without treating every known fact as universally usable.

The graph can reference accounts, income, obligations, assets, debts, goals, skills, verified credentials, currencies, rewards, subscriptions, preferences, research eligibility, HIN contributions, SunRey participation and other authorized context. The graph should store or reference metadata that makes each relationship governable.

Relationship metadata	Question answered
Source	Where did the fact or relationship originate?
Verification	How strongly is it supported?
Sensitivity	What privacy treatment is required?
Purpose	For which uses may this edge participate?
Consent state	Is authorization current, expired, withdrawn or pending?
Jurisdiction	Which local rules and data-residency constraints apply?
Permitted agent/model	Which computational actors may use it?
Expiry	When must the authorization or fact be refreshed?

Graph safety principle

Knowing something never implies permission to use it. The Purpose Firewall and consent rules remain authoritative over the graph.

USE WITHOUT UNNECESSARY POSSESSION

10. Privacy Clean Room & Compute-to-Data

A core HIN design move is to sell or authorize computation and defined outputs rather than indiscriminate copies of raw personal information.

BUYER REQUEST	ELIGIBILITY	CONSENT	CLEAN ROOM	AUTHORIZED OUTPUT	COMPENSATION
---------------	-------------	---------	------------	-------------------	--------------

Compute-to-data: the buyer can receive a permitted result while raw sensitive data remains protected.

A Privacy Clean Room receives an approved query, model or aggregation job; resolves the applicable participant cohort; verifies consent and purpose; executes against protected data; and releases only the allowed result. The result may be an aggregate statistic, eligibility proof, cohort count, model output, attestation or other defined artifact. Raw data access is false by default and any exception would require a separate high-control product.

Stage	Controls
Input controls	Approved model/query, signed requester identity, purpose, privacy budget, jurisdiction and data categories.
Execution controls	Isolated environment, policy enforcement, logging, output constraints and model/version references.
Output controls	Aggregation thresholds, permitted fields, privacy filters and evidence receipt.
Economic controls	Metering, contribution attribution, compensation rules and settlement evidence.

Compute-to-data principle

The economic object can be the right to compute or receive a verified output - not ownership of the underlying dossier.

MACHINE-READABLE RIGHTS

11. Data Rights Packets

A Data Rights Packet (DRP) makes permissioned information markets legible by packaging exactly what can be used, how, where, and under which economic terms.

DRP field	Meaning
Data categories	The exact categories or derived attributes in scope.
Cohort definition	Eligibility conditions and minimum contributor count.
Permitted purpose	The specific allowed economic or research purpose.
Authorized compute	Allowed query, model or aggregation class.
Raw data access	Default FALSE.
Jurisdiction	Where participant, buyer and compute environment may be located.
Expiry / revocation	Time window and withdrawal handling.
Compensation	Minimum or clearing compensation; permitted settlement methods.
Resale / derivative use	Explicitly allowed or prohibited.
Privacy budget	Optional limits governing aggregate or model outputs.

The DRP concept moves the marketplace from “buy this dataset” to “acquire this narrowly defined, policy-aware right.” That shift is central to SunRey differentiation because it makes purpose, rights and privacy part of the market object rather than terms hidden in a separate contract.

Market design

Rights travel; raw sensitive data does not need to.

VERIFICATION ARCHITECTURE

12. Contribution Attestation Mesh

Human contributions are not all verified in the same way. SunRey uses contribution-specific evidence classes rather than a single universal oracle.

Contribution class	Representative evidence
Research	Publication records, institutional evidence, study receipts, cohort participation, signed completion records.
Education & skills	Credential issuers, certificates, assessments and verified learning records.
Work & professional contribution	Employer, client or platform receipts; signed work artifacts; provenance and outcome evidence.
Computation participation	Signed job receipts, model execution receipts, usage metering and permitted-output records.
Authorized information contribution	Consent receipt, data-rights state, usage receipt, clean-room execution and output evidence.
User-declared preferences/goals	Self-attestation may be valid as a preference signal but does not automatically become independently verified fact.

The mesh preserves provenance: which issuer, institution, provider or compute environment produced the evidence; how that evidence was transformed; what policy evaluated it; and whether independent corroboration was required. This creates a route from human participation to verifiable economic contribution without requiring one monolithic identity or oracle provider.

Verification principle

Self-attestation can be an input. It does not automatically become a verified economic fact where independent evidence is required.

FROM EVENT TO ECONOMIC CLAIM

13. Proof of Contribution & Canonical Contributions

Before a contribution can be valued, SunRey needs a durable answer to a basic question: what exactly happened once?

Proof of Contribution is the evidence layer showing that an authorized contribution occurred, was attributable to the correct participant, was permitted for the relevant purpose, produced an eligible outcome, and has not already been monetized as the same event. The proof can reference hashes, consent state, usage receipts, output receipts, provenance and compensation without writing the underlying sensitive record to a public chain.

Claim field	Purpose
Canonical participant	Which human economic identity owns the contribution event?
Canonical event identity	What unique economic event occurred?
Lineage	Which sources and transformations support it?
Rights references	Which consent, rights and purpose objects authorized the event?
Verification status	What evidence class and confidence support the claim?
Challenge state	Is the claim accepted, disputed, under review or superseded?
Monetization state	Has this economic event already been compensated or used for an issuance proposal?

Canonical claim

Multiple observations can support one contribution. They do not automatically become multiple monetizable contributions.

ECONOMIC INTEGRITY

14. Anti-Double-Counting & Sybil Resistance

The value layer must resist two distinct forms of inflation: duplicating the same contribution and multiplying identities around the same human participant.

A research contribution might appear in a publisher database, university repository, researcher registry and aggregator. Those records can be four pieces of corroborating evidence for one contribution rather than four payable events. Likewise, one human may control multiple wallets; wallet multiplicity does not create multiple human economic contributions.

Control	Role
Contribution fingerprinting	Canonical event identifiers, source lineage and duplicate fingerprints identify repeated representations of one event.
Participant uniqueness	Human economic identity separates contribution attribution from wallet count.
Credential assurance	Credential references and identity assurance strengthen uniqueness without requiring public legal identity.
Signed receipts	Work, research, computation or data-use receipts establish specific completed events.
Fraud signals	Anomaly, velocity and relationship signals can escalate review without becoming automatic human-worth scoring.
Challenge workflow	Conflicting evidence can be disputed and resolved before value or compensation is finalized.

Sybil principle

A participant can have multiple accounts or wallets; the system should not allow those technical identities to multiply one human contribution.

CONTRIBUTION VALUATION

15. Personal Economic Value Engine (PEVE)

PEVE is the valuation layer behind “The Currency of You.” It estimates the market value of a specific, verified and authorized contribution in a specific context.

Illustrative canonical model

$V_h = f(D, S, V, F, U, P) - C_p - C_c$, where D = demand, S = scarcity, V = verification quality, F = freshness, U = economic or research utility, P = permitted usage scope, C_p = privacy/sensitivity cost, and C_c = compliance cost.

Earlier SunRey architecture work expands this research framework with completeness, geographic relevance and outcome contribution. The important point is not a fixed formula. It is the explicit separation of value drivers, privacy costs and compliance costs under a versioned methodology that can be calibrated, challenged and audited.

Factor	Question
Demand	How strongly does an authorized buyer or use case need this contribution?
Scarcity	How substitutable or rare is the relevant contribution in the eligible market?
Verification quality	How strong and independent is the evidence?
Freshness	How time-sensitive is the contribution?
Utility	What legitimate economic, analytical or research value does it create?
Permission scope	How broad or narrow is the authorized use?
Privacy/sensitivity cost	What additional safeguards, minimization or risk cost does the use require?
Compliance cost	What legal, operational and audit burden is associated with the use?

PEVE CONTROLS

16. Valuation Governance & Sensitive Categories

A contribution-value model can become dangerous if it quietly becomes a social ranking system. SunRey therefore treats methodology governance as part of the architecture.

Each PEVE methodology should be versioned, explainable, calibrated against actual market behavior, subject to bias and sensitivity testing, and constrained by jurisdiction. Protected or highly sensitive traits should not become direct desirability multipliers. Sensitive categories warrant stronger purpose controls and privacy treatment, not automatic pressure for higher monetization.

Governance control	Requirement
Method versioning	Every valuation must identify the exact methodology and parameter version.
Factor provenance	Inputs should be traceable to authorized sources and evidence.
Bias testing	Methods should be tested for prohibited or unjustified proxy effects.
Sensitive-category firewall	Protected traits and human-worth constructs cannot become valuation shortcuts.
Market validation	Research values should be checked against real authorized demand rather than treated as intrinsic truth.
Jurisdiction packs	The same contribution may have different permitted uses or cost structures by location.
Human review / challenge	High-consequence valuations should support dispute, explanation and correction workflows.

PEVE boundary

PEVE can estimate contribution value. It cannot determine a person's worth, set SunRey market price, or independently create SunRey supply.

NATIVE HUMAN-ECONOMY ASSET

17. SunRey Coin: Economic Role

SunRey Coin is the native economic coordination asset for the Human Information Network and broader human economic layer.

Its role is to coordinate network participation rather than to collateralize a person or raw personal data. Depending on legal and product permissions, SunRey Coin can support settlement, rewards, network utility, information-market transactions, compute requests, attestation activity and other forms of authorized human economic participation.

Economic role	Illustrative use
Contribution compensation	A permitted settlement option for completed, rights-governed contribution.
Research rewards	Compensation or incentives for eligible research/product-testing activity.
Network participation	Rewards or utility associated with approved ecosystem contribution.
Compute / information markets	Settlement for authorized requests, metered computation or rights transactions.
Transfers	Native asset transfer where legally permitted.
Exchange trading	Market trading only where listing, custody and jurisdictional permissions exist.
Access relationship	Participation may influence governed Access entitlements, but Access remains a distinct non-cash entitlement state.

Not data collateral

The intended value driver is useful network activity - not a simplistic claim that a person's raw data "backs" the coin.

ONE COIN REMAINS ONE COIN

18. Fungibility, Compensation & Market Price

The architecture preserves fungibility: one SunRey Coin should not have a different exchange value because of who owns it.

The “economic value of you” therefore affects the compensation basis for a specific authorized contribution, not the market exchange rate of each coin held by that participant. Two people can receive different quantities of SunRey for different contributions while the units themselves remain fungible once issued.

Object	Characteristics	Economic treatment
Contribution A	High demand, scarce, strongly verified, narrow permission scope	Higher contribution valuation may justify higher compensation under policy.
Contribution B	Common, lower-demand, less time-sensitive contribution	Lower contribution valuation may justify lower compensation.
SunRey Coin	Fungible native asset	Units do not carry owner-specific exchange values.
Exchange price	Market-clearing price in permitted venues	Cannot be inferred directly from PEVE or a personal profile.

This boundary avoids turning token ownership into a persistent personal score. It also allows the economic network to price authorized contributions dynamically while keeping the settlement asset legible for accounting, custody and exchange.

Separation

Contribution value determines what a contribution may earn. Market price determines what the fungible asset trades for. They are different mechanisms.

INFORMATION IS NOT MONEY

19. The Evidence-to-Money Firewall

The most important monetary safety principle is that no information system may silently become an issuance authority.

RAW DATA	OBSERVATION	VERIFIED FACT	ECONOMIC CLAIM	PEVE VALUATION	MONETARY PROPOSAL	GOVERNED ISSUANCE
----------	-------------	---------------	----------------	----------------	-------------------	-------------------

Every stage can add evidence or interpretation; only the final governed protocol path may change native supply.

Raw personal data cannot mint. An observation cannot mint. A verified economic fact cannot mint. A canonical claim cannot mint. PEVE cannot mint. An oracle, AI agent, API, frontend, exchange, identity provider, operational database or clean-room job cannot mint. These systems may create evidence, calculations or proposals; they do not possess sovereign monetary authority.

Plane	Authority
Information authority	Establishes what evidence exists and what claim is supported.
Rights authority	Establishes whether the evidence may be used for the requested purpose.
Valuation authority	Applies a governed method to estimate contribution value.
Monetary policy authority	Determines permitted conversion, caps, supply rules and other economic parameters.
Protocol consensus	Finalizes valid native monetary state transitions.
Market	Discovers exchange price after issuance; market price does not recursively authorize new issuance.

FROM VALUE TO SETTLEMENT

20. Governed Monetary Conversion & Issuance

Rights-governed evidence can become verified contribution; verified contribution can be valued; valuation can inform a governed conversion proposal. Those steps are intentionally separate.

RIGHTS- GOVERNED EVIDENCE	VERIFIED CONTRIBUTION	PEVE / VALUE	GOVERNED CONVERSION	MONETARY AUTHORITY	SUNREY SETTLEMENT
---------------------------------	--------------------------	--------------	------------------------	-----------------------	----------------------

Canonical human-economy path. Production coefficients are governance inputs, not hard-coded assumptions.

Production architecture should use typed, versioned economic parameter packages, explicit supply guards, conversion policy references, governance evidence and audit-ready policy commitments. Engineering fixtures or simulation values must never be promoted into production authority merely because a generic “production” flag is enabled.

This preserves an important constitutional boundary: the software can be prepared to accept future tokenomics and conversion decisions without inventing those decisions. The current SunRey architecture intentionally leaves real production conversion coefficients and final issuance parameters subject to separate human governance, legal review and launch authorization.

Monetary constitution

Valuation is an input to policy. Policy is not a price feed. Price is not an issuance rule. Governance and protocol consensus remain the final authorities for supply-changing transitions.

DEMAND SIDE OF HIN

21. Enterprise and Research Participation

The HIN becomes economically meaningful only when authorized buyers can request useful, bounded outputs under terms the participant can understand and control.

Enterprise request	Example	HIN response
Research cohort	“Find eligible participants matching defined criteria and run an approved analysis.”	Cohort rights + consent + clean-room compute + aggregate result.
Credential verification	“Verify that this participant possesses a qualifying credential.”	Attestation or eligibility proof; no unnecessary credential dossier.
Consumer demand intelligence	“Estimate demand among users who explicitly permitted this use.”	Purpose-scoped aggregate output with privacy threshold.
Product testing	“Recruit authorized participants and compensate verified completion.”	Consent + task receipt + Proof of Contribution + settlement.
AI evaluation	“Run an approved model against a permitted cohort without receiving raw records.”	Compute-to-data job + metered output + provenance receipt.

This model creates a marketplace in narrowly defined rights and computation rather than downloadable dossiers. Enterprises gain clearer provenance and policy context; users gain visibility, revocability where applicable and an economic participation path; SunRey gains a network whose core transaction object includes purpose and rights.

Demand-side rule

Enterprise demand does not override user permission, privacy thresholds, legal capability or output constraints.

INTELLIGENCE WITHOUT SOVEREIGN AUTHORITY

22. AI Agents Inside the HIN

AI can make the HIN more useful by finding relevant context, opportunities and relationships. It must remain subordinate to rights, policy and explicit capability boundaries.

A SunRey Financial Agent may use the Personal Economic Graph to reason over authorized financial and personal context, identify a research opportunity, explain a potential economic benefit, or recommend that a user grant a specific permission. But the agent does not receive unrestricted access to every data category and does not directly move money or activate rights.

AI dimension	Rule
Allowed AI role	Classification, entity-resolution suggestions, opportunity discovery, explanation, anomaly detection, evidence summarization and user-facing analysis.
Capability boundary	Agent token defines allowed proposal types, data categories, accounts, amount limits, jurisdiction, expiry and revocation.
Purpose boundary	A model permitted for financial personalization may not automatically use the same context for advertising or training.
Execution boundary	AI proposes; deterministic policy and required human approval govern the action.
Monetary boundary	AI cannot authorize issuance, set monetary policy or elevate its own permissions.

AI principle

AI is an analyst and proposer - not the human, not the rights authority, and not the sovereign monetary authority.

TRUST ARCHITECTURE

23. Privacy, Security, Jurisdiction & Audit

A rights-governed information economy requires stronger evidence of control than a conventional “privacy policy.” The controls must be enforceable and reconstructable.

Control	Requirement
Data minimization	Collect or expose only what is required for the authorized purpose.
Encryption & key separation	Protected storage, distinct key purposes and workload-bound access.
Purpose limitation	Every sensitive operation is bound to a declared purpose.
Jurisdiction state	Location, legal entity, product capability and policy version are machine-readable.
Immutable evidence	Rights, policy, execution and compensation receipts support reconstruction of what happened.
Revocation handling	Stops future use as required while preserving append-only historical proof of previously valid events.
Relationship authorization	Access to a person, dataset or graph relationship does not grant unrestricted adjacent access.
Red-team scope	Privacy attacks, inference attacks, Sybil/economic attacks, application attacks and authority-escalation paths require dedicated testing.

Trust proposition

The HIN should be auditable enough to prove why a use was permitted without publishing the sensitive material that permission protected.

END-TO-END EXAMPLE

24. Illustrative Use Case I - Research Participation

A research organization wants to run an approved analysis on a cohort with defined eligibility characteristics. The SunRey architecture can support the request without transferring a raw user dossier.

Step	Stage	What happens
1	Buyer request	Researcher declares cohort, purpose, model/query, jurisdiction, budget, output and reuse limits.
2	Eligibility	HIN identifies potentially eligible pseudonymous participants using authorized graph context.
3	Consent	Each participating user grants or confirms the specific research permission.
4	Compute	Approved job executes in a clean room near protected source data.
5	Verification	Execution receipts, data-rights state and outcome evidence form contribution attestations.
6	Output	Researcher receives the permitted aggregate or approved result, not unrestricted raw data.
7	Valuation	PEVE estimates the value of each eligible verified contribution under the applicable method.
8	Settlement	Compensation is paid in a permitted form; if SunRey is used, monetary conversion follows governed issuance/settlement rules.
9	Proof	Contribution, rights, policy, compensation and output receipts become auditable evidence.

Result

The researcher buys an authorized result. The participant retains rights over the underlying information and can participate economically in the completed use.

VERIFIED HUMAN CONTRIBUTION

25. Illustrative Use Case II - Skills & Credentials

A participant has professional expertise and verified credentials. The economic network should distinguish the credential itself, proof of the credential, and any compensated contribution built on that expertise.

For a simple eligibility request, the HIN may return an attestation that a credential threshold is satisfied without transferring the full educational or employment history. For a paid expert task, the contribution object becomes the completed task or verified output, supported by credential references, work receipts and provenance.

Layer	Example
Credential source	Issuer or trusted verification path establishes the credential reference.
Permission	Participant authorizes the requested verification or task context.
Purpose	Eligibility, expert recruitment, research or another defined use.
Contribution	Completed expert response, review, annotation, research task or other verifiable work.
Attestation	Signed receipts and output evidence support verification.
PEVE	Demand, scarcity, verification, utility and permission scope inform contribution value.
Compensation	Fiat, SunKey or another permitted reward can settle the specific contribution.
Privacy boundary	Full employment history, legal identity or unrelated credentials are not automatically disclosed.

Economic meaning

Verified expertise can create value without creating a permanent score of the expert.

INTENT WITHOUT SURVEILLANCE

26. Illustrative Use Case III - Permissioned Consumer Intent

Consumer intent can be economically valuable, but SunRey treats it as an explicitly permissioned contribution rather than covert behavioral surveillance.

A user may choose to share a purchase horizon, product category, travel interest, price sensitivity or another declared preference with a specific class of merchants or research buyers. The HIN can package that permission as a narrow rights object, enforce duration and purpose, and support aggregate market intelligence or targeted offers without granting open-ended access to unrelated behavior.

Element	Illustrative treatment
User declaration	"I am shopping for an EV in the next 90 days."
Permission scope	Automotive offers and aggregate demand research; no unrelated advertising.
Duration	90 days, renewable only by the user.
Data access	Declared intent + limited authorized context; raw unrelated transaction history stays protected.
Compute	Eligible merchants or research jobs receive a permitted score, cohort inclusion or offer route.
Economic participation	The user may receive an offer, reward, research compensation or other approved benefit.
Revocation	Future use stops when permission expires or is withdrawn, subject to applicable rules.
Audit	Receipts show which requester used which permission for which purpose.

Difference from ad-tech

The user declares the economic relationship and the purpose; the network does not assume that observed behavior is an unlimited asset for downstream use.

WHY THE MODEL CAN COMPOUND

27. Network Effects & Economic Utility

The HIN network effect is stronger than “more wallets create more value” only if the architecture preserves trust and produces measurable utility for participants and authorized demand for buyers.

Network effect	Economic consequence
More trusted participants	Increase the breadth of authorized contribution and eligible cohorts.
Richer permissioned context	Improves agent personalization, research eligibility and enterprise computation.
More enterprise/research demand	Creates more compensated contribution opportunities and protocol utility.
Better verification	Improves confidence, reduces fraud and makes outputs more useful.
Better rights tooling	Lowers transaction friction for consent, purpose, jurisdiction and audit.
More useful SunRey activity	Increases legitimate settlement and network participation without requiring raw-data collateral claims.

The moat depends on trust. If users perceive the HIN as surveillance or one-way extraction, the network effect reverses. The system therefore has to make permissions visible, revocation meaningful where applicable, compensation understandable, and data use auditable.

Compounding loop

Trust -> participation -> verified contribution -> useful authorized outputs -> compensation and better services -> deeper trust.

DISTINCTIVE CLAIM CLUSTERS

28. Technical Differentiation & IP Prospects

SunRey does not need to claim invention of encryption, blockchains, clean rooms, identity systems or valuation algorithms individually. The differentiation is primarily in how these mechanisms are integrated as a rights-governed human economic architecture.

Potential claim cluster	Distinctive integration
Rights-governed contribution pipeline	Person -> permission -> verified contribution -> authorized use -> compensation, with explicit separation from human worth.
Contribution-specific attestation mesh	Evidence classes vary by research, work, education, compute and authorized information use.
Canonical contribution + anti-duplication	Multiple evidence records resolve to one economic contribution and monetization state.
PEVE + monetary firewall	Versioned contribution valuation remains upstream of, but cannot directly control, native issuance.
Compute-to-data rights packets	Purpose, model, jurisdiction, output, privacy budget, compensation and derivative rights become machine-readable market state.
Pseudonymous identity with economic uniqueness	Separate wallet/login/governance identities while preserving participant-level anti-Sybil constraints.
Proof-bound privacy model	Evidence, rights and policy commitments explain economic settlement without publishing the raw dossier.

IP caution

These are technical differentiation themes, not legal conclusions on patentability. Formal claims require independent prior-art search and counsel analysis.

WHAT SOFTWARE CANNOT DECIDE FOR ITSELF

29. Governance & Production Boundaries

The architecture can encode constraints and evidence, but production rights, tokenomics, data-market permissions and regulatory status require external decisions and human authorization.

Boundary	Required discipline
Production monetary parameters	Real conversion coefficients, issuance caps, supply policy and other tokenomics cannot be inferred from simulations.
Legal classification	SunRey Coin, compensation models, research markets and information-rights products require jurisdiction-specific analysis.
Consent validity	Technical consent objects must reflect applicable legal and contractual requirements.
Sensitive-data use	Health, biological, psychological, location and other high-sensitivity categories require the strongest legal and product controls.
Enterprise data rights	Provider licenses and buyer contracts must match the rights represented by the protocol.
Security assurance	Independent security review, key-management evidence, privacy testing and operational readiness remain launch gates.
AI governance	Model approval and monitoring cannot replace required human, compliance or governance approvals.
Mainnet / live activation	Code existence is not authorization to activate live financial, exchange or data-market capabilities.

Production doctrine

No single dataset, provider, AI model, operator, database, market price or software flag should be able to silently create economic or monetary authority.

30. Conclusion

The defining SunRey idea is not that a human being can be tokenized. It is that a human can become the authority over the rights surrounding their economic information and contribution.

The Human Information Network turns this principle into architecture. Identity can be pseudonymous and function-specific. Sensitive source data can remain in protected vaults. Consent and purpose can be granular, time-limited and auditable. Clean rooms can bring approved computation to data. Contribution attestations and canonical claims can establish what occurred without multiplying the same event. PEVE can estimate the market value of a defined contribution without becoming a social score. SunRey Coin can provide a fungible coordination and settlement layer without claiming that the person or their raw data backs the asset.

The most consequential design decision is the separation of authorities. Information may establish a fact. Rights determine whether it may be used. Verification determines whether the contribution is credible and unique. PEVE estimates economic value. Monetary governance determines what conversion, if any, is permitted. Protocol consensus establishes final monetary state. The market discovers exchange price. No single layer is allowed to collapse the others.

Final thesis

The Currency of You is a rights-governed economic architecture in which people can authorize, verify and participate in the value created by their contributions - without surrendering their identity, raw data, or human worth to the monetary system.

For a post-AI economy, that is the larger proposition: human economic participation can remain first-class even as automation expands, provided the network values authorized contribution rather than treating people as data inventory.

REFERENCE

Appendix A - Glossary & Source Basis

Term	Definition
HIN	Human Information Network - permission-aware network for verified human contribution, rights, computation and economic participation.
SunRey Coin	Native economic coordination asset for the human economic layer.
PEVE	Personal Economic Value Engine - versioned valuation of a specific authorized contribution, not human worth.
Personal Data Vault	Protected segmented storage for user-linked sensitive source data.
Purpose Firewall	Authorization layer that determines whether a requested use is permitted for its declared purpose.
Consent Ledger	Granular, time-limited, revocable and auditable authorization state.
Privacy Clean Room	Controlled environment that executes approved computation near protected data and releases permitted outputs.
Proof of Contribution	Evidence that an authorized, attributable contribution occurred and produced an eligible economic outcome.
DRP	Data Rights Packet - machine-readable package of scope, purpose, compute, jurisdiction, privacy and compensation rights.
Canonical Contribution	Unique human economic event resolved across multiple observations and sources.
Monetary Issuance Authority	Governed protocol path permitted to finalize supply-changing native-asset transitions.

Primary SunRey source basis

- SunRey Comprehensive Business Plan - September 2026 (Sections 3-4).
- SunRey Strategy, Product Architecture, Compliance Framework & Launch Valuation - August 2026 (Sections 3, 5-9, 14, 19-22).
- SunRey Economic Awareness & Sovereign Monetary Architecture - September 2026 (Sections 2, 4-5, 7-9, 11-12).
- Solstice Comprehensive Product, Architecture, API, Compliance & Growth Systems Report - August 14, 2026 (legacy naming; Sections 10-13).
- Solstice SFF 2.0 Architecture Summary - August 2026 (PEVE and first-class economic intelligence components).
- SunRey Blockchain & Universal Economic Exchange - Technical Architecture and Novel Market Design - August 2026.
- SunRey Architecture & Production-Candidate Build Report - August 2026 (human-economy monetary constitution and permanent authority boundaries).

Terminology note: historical Solstice/Pyramid references are normalized here to current SunRey naming where the concepts remain part of the present architecture.

Technical and legal note: This paper is a conceptual architecture document, not legal, regulatory, securities, tax, investment or patent advice. Production capabilities require current jurisdiction-specific review, service-provider agreements, security approval, governance decisions and explicit activation.
